The half-life of the $\beta\beta_{2\nu}$ decay of ^{160}Gd , a process which was previously reported as theoretically forbidden in the context of the pseudo SU(3) model, is estimated by including the pairing interaction. Thus, different occupations can be mixed by the interaction opening new channels for the decay. Explicit expressions are presented for the mixing induced by the pairing force. Matrix elements for the $\beta\beta_{2\nu}$ and $\beta\beta_{0\nu}$ decays are calculated, in the present pseudo SU(3) approach, by assuming both a dominant component in the wave function of the ground state of ^{160}Gd and a more general model space. The results, of the calculated $\beta\beta$ half-lives, suggest that the planned experiments would succeed in detecting the $\beta\beta_{2\nu}$ decay of ^{160}Gd and, eventually, would improve the limits for the zero neutrino mode.

I. INTRODUCTION

The flux of solar and atmospheric neutrinos has been measured with increasing precision, and the data offer direct evidence on the presence of neutrino oscillations [1, 2]. These findings imply that at least neutrinos of some flavor should be massive. The difference between the square of the masses of neutrinos belonging to different families can be extracted from the experimental data, relying on theoretical models of mass hierarchies and textures [3]. On the other hand, their absolute scale cannot be obtained from these experiments.

The neutrinoless double beta decay ($\beta\beta_{0\nu}$), if detected, would provide the complementary information needed to determine neutrino masses, and would also offer definitive evidence that the neutrino is a Majorana particle, i.e. that it is its own antiparticle [4, 5].

Theoretical nuclear matrix elements are needed to translate experimental half-life limits, which are available for many $\beta\beta$ -unstable isotopes [7, 8], into constraints for the effective Majorana mass of the neutrino and, eventually, for the contribution of right-handed currents to the weak interactions. Thus, these matrix elements are essential to understand the underlying physics.

The two neutrino mode of the double beta decay ($\beta\beta_{2\nu}$) is allowed as a second order process in the standard model. It has been detected in ten nuclei [7, 8] and it has served as a test of a variety of nuclear models [5]. The calculation of the $\beta\beta_{2\nu}$ and $\beta\beta_{0\nu}$ matrix elements requires the use of different theoretical methods. Therefore a successful prediction of the former cannot be considered a rigorous test of the latter [6]. However, in most cases it is the best available proof we can impose to a nuclear model used to predict the $\beta\beta_{0\nu}$ matrix elements. When possible, the test should also include the calculation of the energy spectra, electromagnetic transitions and particle transfer observables, in the neighborhood of the double beta emitters.

Many experimental groups have reported measurements of $\beta\beta$ processes [7, 9]. In direct-counting experiments the analysis of the sum-energy spectrum of the emitted electrons identifies the different $\beta\beta$ -decay modes [10].

The pseudo SU(3) approach has been used to describe many low-lying rotational bands, as well as BE(2) and B(M1) intensities in rare earth and actinide nuclei, both with even-even and odd-mass numbers [11, 12, 13, 14, 15, 16]. The $\beta\beta$ half-lives of some of these parent nuclei to the ground and excited states of the daughter were evaluated for the two and zero neutrino emitting modes [17, 18, 19, 20, 21] using the pseudo SU(3) scheme. The predictions were found to be in good agreement with the available experimental data for ^{150}Nd and ^{238}U .

Based on the selection rules of the simplest pseudo SU(3) model, the theory predicts the complete suppression of the $\beta\beta$ decay for the following five nuclei: ^{154}Sm , ^{160}Gd , ^{176}Yb , ^{232}Th and ^{244}Pu [17]. It was expected that these

forbidden decays would have, in the best case, matrix elements that would be no greater than 20% of the allowed ones, resulting in the increase, by at least one order of magnitude, of the predicted half-life [21]. Experimental limits for the $\beta\beta$ decay of ^{160}Gd have been reported [22, 23]. Recently it was argued that the strong cancellation of the 2ν mode in the $\beta\beta$ decay of ^{160}Gd would suppress the background for the detection of the 0ν mode [24].

In the present contribution we extend the previous research [17, 18, 19, 20, 21] and evaluate the $\beta\beta$ half-lives of ^{160}Gd using the pseudo SU(3) model. While the 2ν mode is forbidden when the most probable occupations are considered, states with different occupation numbers can be activated by the pairing interaction. The amount of this mixing is evaluated, and the possibility of observing the $\beta\beta$ decay in ^{160}Gd is discussed for both the 2ν and 0ν modes. The analysis is performed firstly for the extreme case of a single active configuration in the initial nucleus, and afterwards, the results are compared with the ones obtained by enlarging the model space.

The paper is organized as follows. In Section II the pseudo SU(3) formalism and the model Hamiltonian are briefly reviewed. In Section III the ^{160}Gd and ^{160}Dy ground state wave functions are built. Section IV and V contain the explicit formulae needed to evaluate, using the pseudo SU(3) scheme, the $\beta\beta_{2\nu}$ and $\beta\beta_{0\nu}$ matrix elements, respectively. In Section VI the ^{160}Gd $\beta\beta$ nuclear matrix elements and half-lives are presented. Conclusions are drawn in the last Section.

II. THE PSEUDO SU(3) FORMALISM

In order to obtain a microscopic description of the ground states of ^{160}Gd and ^{160}Dy we will use the pseudo SU(3) model, which successfully describes collective excitations in rare earth nuclei and actinides [11, 12, 13, 14, 15, 16, 25], and it has been used to evaluate the half-lives of the $\beta\beta_{2\nu}$ decay to the ground and excited states and $\beta\beta_{0\nu}$ decays of six heavy deformed nuclei [17, 18, 19, 20, 21], and the double electron capture decays in other three nuclei [26].

In the pseudo SU(3) shell model coupling scheme [27] normal parity orbitals with quantum numbers (η, l, j) are mapped to orbitals of another harmonic oscillator with $(\tilde{\eta} = \eta - 1, \tilde{l}, \tilde{j})$. This set of orbitals, with $\tilde{j} = j = \tilde{l} + \tilde{s}$, pseudo spin $\tilde{s} = 1/2$ and pseudo orbital angular momentum $\tilde{l}$, define the so-called pseudo space. For configurations of identical particles occupying a single j orbital of abnormal parity, a simple characterization of states is made by means of the seniority coupling scheme.

The first step in the pseudo SU(3) description of a given nucleus consists in finding the occupation numbers for protons and neutrons in the normal and abnormal parity states $n_\pi^N, n_\nu^N, n_\pi^A, n_\nu^A$ [17]. These numbers are determined filling the Nilsson levels from below, as discussed in [17].

For even-even heavy nuclei it has been shown that if the residual neutron-proton interaction is of the quadrupole type, regardless of the interaction in the proton and neutron spaces, the most important normal parity configurations are those with highest spatial symmetry $\{\tilde{f}_\alpha\} = \{2^{n_\alpha^N/2}\}$ [25]. This statement is valid for yrast states below the backbending region. It implies that $\tilde{S}_\pi = \tilde{S}_\nu = 0$, i.e. only pseudo spin zero configurations are taken into account.

Additionally in the abnormal parity space only seniority zero configurations are taken into account. This simplification implies that $J_\pi^A = J_\nu^A = 0$. This is a very strong assumption quite useful in order to simplify the calculations.

Many-particle states of n_α active nucleons in a given normal parity shell η_α , $\alpha = \nu$ or π , can be classified by the following chains of groups:

$$\begin{array}{ccccccc} \{1^{n_\alpha^N}\} & \{\tilde{f}_\alpha\} & \{f_\alpha\} & \gamma_\alpha(\lambda_\alpha, \mu_\alpha) & \tilde{S}_\alpha & K_\alpha & \tilde{L}_\alpha & J_\alpha^N \\ U(\Omega_\alpha^N) \supset U(\Omega_\alpha^N/2) \times U(2) \supset SU(3) \times SU(2) \supset SO(3) \times SU(2) \supset SU_J(2), \end{array} \quad (1)$$

where above each group the quantum numbers that characterize its irreps are given and γ_α and K_α are multiplicity labels of the indicated reductions. The most important configurations are those with the highest spatial symmetry [25, 28], namely those with pseudo spin zero.

The model Hamiltonian contains spherical Nilsson single-particle terms for protons ($H_{sp,\pi}$) and neutrons ($H_{sp,\nu}$), the quadrupole-quadrupole ($\tilde{Q} \cdot \tilde{Q}$) and pairing interactions (V_{pair}), as well as three ‘rotor-like’ terms which are diagonal in the SU(3) basis.

$$H = H_{sp,\pi} + H_{sp,\nu} + V_{pair} - \frac{1}{2} \chi \tilde{Q} \cdot \tilde{Q} + a K_J^2 + b J^2 + A_{asym} \hat{C}_2. \quad (2)$$

This Hamiltonian can be separated into two parts: the first one includes Nilsson single-particle energies and the pairing and quadrupole-quadrupole interactions ($\tilde{Q}$ is the quadrupole operator in the pseudo SU(3) space). They are the basic components of any realistic Hamiltonian [29, 30] and have been widely studied in the nuclear physics literature, allowing their respective strengths to be fixed by systematics [29, 30]. In the second one there are three

rotor terms used to fine tune the moment of inertia and the position of the different K bands. The SU(3) mixing is due to the single-particle and pairing terms.

The three ‘rotor-like’ terms have been studied in detail in previous papers where the pseudo SU(3) symmetry was used as a dynamical symmetry [25]. In recent works, a , b , and A_{asym} were the only parameters used to fit the spectra [13, 15, 16, 31, 32].

The spherical single-particle Nilsson Hamiltonian is

$$H_{sp} = \hbar\omega_0(\eta + \frac{3}{2}) - \kappa\hbar\omega_0\{2\vec{l} \cdot \vec{s} + \mu\vec{l}^2\} = \sum_i \epsilon(\eta_i, l_i, j_i) a_i^\dagger a_i \quad (3)$$

with parameters [29]

$$\begin{aligned} \hbar\omega_0 &= 41A^{-1/3}[\text{MeV}], \quad \kappa_\pi = 0.0637, \quad \kappa_\nu = 0.0637, \\ \mu_\pi &= 0.60, \quad \mu_\nu = 0.42, \end{aligned} \quad (4)$$

The pairing interaction is

$$V_{pair} = -\frac{1}{4}G \sum_{j,j'} a_j^\dagger a_{\bar{j}}^\dagger a_{\bar{j}'} a_{j'} \quad (5)$$

where $\bar{j}$ denotes the time reversal partner of the single-particle state j , and G is the strength of the pairing force. In principle we can start with an isospin invariant pairing force, which contains proton-proton, neutron-neutron and proton-neutron terms with equal strengths. However, in the limited Hilbert space employed there are not protons and neutrons in the same orbitals, and the proton-neutron pairing term is ineffective. In recent works [13, 15, 16, 31, 32], the pairing coefficients $G_{\pi,\nu}$ were fixed following [29, 30], with values:

$$G_\pi = \frac{21}{A} = 0.132 \text{ MeV}, \quad G_\nu = \frac{17}{A} = 0.106 \text{ MeV}. \quad (6)$$

III. THE GROUND STATE OF ^{160}Gd AND ^{160}Dy

In this section we shall present the relevant results of the pseudo SU(3) model, for the wave functions of the participant nuclei. We shall assume, in subsection (III.A), that the wave function describing the ground state of ^{160}Gd has only one component and that the corresponding wave function for ^{160}Dy has two components connected by the pairing interaction. This assumption allows us to perform a simple estimation of the double beta decay, as shown in sections IV and V. In subsection (III.B) we shall include other configurations in the model space, to asses the quality of the simplified description.

A. The one-component model

With a deformation of $\epsilon = 0.26$ [33], the most probable occupations for the ^{160}Gd 14 valence protons are 8 particles in normal and 6 particles in unique parity orbitals, and for the 14 valence neutrons are 8 particles in normal and 6 particles in unique parity orbitals.

After the detailed study of $^{156,158,160}\text{Gd}$ isotopes performed in [16, 32], it becomes clear that the pseudo SU(3) model is a powerful tool in the description of heavy deformed nuclei. Up to four rotational bands, with their intra- and inter- band B(E2) transition strengths, as well as B(M1) transitions, were reproduced, with a very good general agreement with the experiment.

The dominant component of the ^{160}Gd ground state wave function [16] is

$$\begin{aligned} |^{160}\text{Gd}, 0^+\rangle &= | (h_{11/2})_\pi^6, J_\pi^A = 0; (i_{13/2})_\nu^6, J_\nu^A = 0 \rangle_A \\ &\quad | \{2^4\}_\pi(10, 4)_\pi; \{2^4\}_\nu(18, 4)_\nu; 1(28, 8)K = 1, J = 0 \rangle_N. \end{aligned} \quad (7)$$

In the first series of papers [17, 18, 19, 20, 21] we have evaluated the $\beta\beta$ matrix elements by taking into account only the leading SU(3) coupled proton-neutron irrep. In recent publications it was shown that the leading irrep represents approximately 60 % of the wave function in even-even Dy and Er isotopes [16, 31].

Assuming a slightly larger deformation for ^{160}Dy , the most probable occupations for 16 valence protons are 10 particles in normal and 6 particles in unique parity orbitals, and for the 12 valence neutrons are 6 particles in normal and 6 particles in unique parity orbitals. A detailed study of $^{160,162,164}\text{Dy}$ isotopes has been performed in [32].

The dominant component of the wave function is

$$|^{160}\text{Dy}, 0^+(a)\rangle = | (h_{11/2})_\pi^6, J_\pi^A = 0; (i_{13/2})_\nu^6, J_\nu^A = 0 \rangle_A \\ |\{2^5\}_\pi(10, 4)_\pi; \{2^3\}_\nu(18, 0)_\nu; 1(28, 4)K = 1, J = 0 \rangle_N.$$

The two neutrino double beta operator annihilates two neutrons and creates two protons with *the same* quantum numbers η, l . It cannot connect the states $|^{160}\text{Gd}, 0^+\rangle$ and $|^{160}\text{Dy}, 0^+(a)\rangle$ and the transition becomes absolutely forbidden. This is the selection rule found in [17].

However, the pairing interaction allows for the mixing between different occupations. In the deformed single particle Nilsson scheme it takes an energy ΔE to promote a pair of protons from the last occupied normal parity orbital to the next intruder orbital. This excited state has 8 protons in normal and another 8 protons in unique parity orbitals, and its wave function has the form

$$|^{160}\text{Dy}, 0^+(b)\rangle = | (h_{11/2})_\pi^8, J_\pi^A = 0; (i_{13/2})_\nu^6, J_\nu^A = 0 \rangle_A \\ |\{2^4\}_\pi(10, 4)_\pi; \{2^3\}_\nu(18, 0)_\nu; 1(28, 4)K = 1, J = 0 \rangle_N.$$

The two neutrino double beta decay of ^{160}Gd can proceed to this state.

As a first approximation, we shall describe the ^{160}Dy ground state as a linear combination of these two states:

$$|^{160}\text{Dy}, 0^+\rangle = a |^{160}\text{Dy}, 0^+(a)\rangle + b |^{160}\text{Dy}, 0^+(b)\rangle, \quad (8)$$

with $|a|^2 + |b|^2 = 1$.

The only term in the Hamiltonian (2) which can connect states with different occupation numbers in the normal and unique parity sectors is the pairing interaction. In the present case, the Hamiltonian matrix has the simple form

$$H = \begin{pmatrix} 0 & h_{pair} \\ h_{pair} & \Delta E \end{pmatrix} \quad (9)$$

with

$$h_{pair} = \langle ^{160}\text{Dy}, 0^+(b) | V_{pair} | ^{160}\text{Dy}, 0^+(a) \rangle = \frac{(-1)^{\tilde{\eta}_\pi + 1} G_\pi}{4} \sqrt{(n_\pi^A + 2)(2j_\pi^A + 1 - n_\pi^A)} \sum_{\tilde{l}_\pi} \sqrt{2(2\tilde{l}_\pi + 1)} \\ \sum_{(\lambda_0 \mu_0)} \langle (0\tilde{\eta}_\pi) 1\tilde{l}_\pi, (0\tilde{\eta}_\pi) 1\tilde{l}_\pi \| (\lambda_0 \mu_0) 10 \rangle_1 \sum_\rho \langle (\lambda^a, \mu^a) 1 0, (\lambda_0 \mu_0) 1 0 \| (\lambda^b \mu^b)_\sigma 10 \rangle_\rho \quad (10) \\ \sum_{\rho_\pi} \begin{bmatrix} (\lambda_\pi^a, \mu_\pi^a) & (\lambda_0, \mu_0) & (\lambda_\pi^b, \mu_\pi^b) & \rho_\pi \\ (\lambda_\nu^a, \mu_\nu^a) & (0, 0) & (\lambda_\nu^b, \mu_\nu^b) & 1 \\ (\lambda^a, \mu^a) & (\lambda_0, \mu_0) & (\lambda^b \mu^b)_\sigma & \rho \\ 1 & 1 & 1 & \end{bmatrix} \langle (\lambda_\pi^a, \mu_\pi^a) ||| [\tilde{a}_0, \tilde{\eta}_\pi, \frac{1}{2}\tilde{a}_0, \tilde{\eta}_\pi, \frac{1}{2}]^{(\lambda_0, \mu_0)} ||| (\lambda_\pi^b, \mu_\pi^b) \rangle_{\rho_\pi}$$

In the above formula $\langle \dots \| \dots \rangle$ denotes the SU(3) Clebsch-Gordan coefficients [34], the symbol $[\dots]$ represents a $9 - \lambda\mu$ recoupling coefficient [35], and $\langle \dots ||| \dots ||| \dots \rangle$ is the triple reduced matrix elements [18].

The lowest eigenstate has an energy

$$E = \frac{\Delta E}{2} \left[1 - \sqrt{1 + \left(\frac{2h_{pair}}{\Delta E} \right)^2} \right], \quad (11)$$

and the components of the ^{160}Dy ground state wave function are

$$a = \frac{h_{pair}}{\sqrt{E^2 + h_{pair}^2}}, \quad b = \frac{E}{\sqrt{E^2 + h_{pair}^2}}. \quad (12)$$

It is a limitation of the present model that ΔE has to be estimated from the deformed Nilsson single particle mean field, instead of the evaluation of the diagonal matrix element of the Hamiltonian (2). The use of seniority zero states for the description of nucleons in intruder orbits inhibits the direct comparison of states with different occupation numbers. A formalism able to describe nucleons in both normal and unique parity orbitals in the same footing is under development [36]. The effect ΔE has on the double-beta-decay half-lives is studied in Section VI.

B. The enlarged model space

In addition to the pseudo SU(3) irreps described in the previous subsection, one has, in an enlarged model space, other potential components to the ground state wave functions of ^{160}Gd and ^{160}Dy . In Tables I and II we are listing the four configurations included in the description of ^{160}Gd and the ones for ^{160}Dy , respectively.

state	n_π^N	n_π^A	n_ν^N	n_ν^A	(λ_π, μ_π)	(λ_ν, μ_ν)	(λ, μ)	$C(\lambda, \mu)$
i_1	8	6	8	6	(10, 4)	(18, 4)	(28, 8)	0.7253
i_2	8	6	10	4	(10, 4)	(20, 4)	(30, 8)	0.4848
i_3	10	4	8	6	(10, 4)	(18, 4)	(28, 8)	0.4066
i_4	10	4	10	4	(10, 4)	(20, 4)	(30, 8)	0.2713

TABLE I: The four configurations included in the description of ^{160}Gd . The number of protons and neutrons, in normal and in intruder orbits and the corresponding pseudo SU(3) irreps are listed. The last column shows their amplitudes, in the wave function of the ground state of ^{160}Gd .

The wave function, of the ground state of ^{160}Gd , is written

$$|^{160}\text{Gd}\rangle = \sum_k C_k^{(i)} |i_k\rangle, \quad (13)$$

and the one of ^{160}Dy , is given by

$$|^{160}\text{Dy}\rangle = \sum_k C_k^{(f)} |f_k\rangle, \quad (14)$$

where the amplitudes $C_k^{(i)}$ and $C_k^{(f)}$ are listed in the last column of Tables I and II, respectively. The mixing matrix

state	n_π^N	n_π^A	n_ν^N	n_ν^A	(λ_π, μ_π)	(λ_ν, μ_ν)	(λ, μ)	$C(\lambda, \mu)$
f_1	10	6	8	4	(10, 4)	(18, 4)	(28, 8)	0.7639
f_2	10	6	6	6	(10, 4)	(18, 0)	(28, 4)	0.5446
f_3	8	8	8	4	(10, 4)	(18, 4)	(28, 8)	0.2690
f_4	8	8	6	6	(10, 4)	(18, 0)	(28, 4)	0.2181

TABLE II: The four configurations included in the description of ^{160}Dy . The configurations and amplitudes are listed following the notation given in the captions to Table I.

(9), for the configurations of Tables I and II, is a 4×4 matrix, with matrix elements h_{pair} of the form (10). The diagonal matrix elements are the energies needed to promote a pair of protons, neutrons or both from a normal to an intruder parity orbital or viceversa. They are estimated from the deformed single particle Nilsson diagrams. The values of ΔE , for the case of ^{160}Gd are 0.54 MeV, 0.81 MeV and 1.35 MeV. The corresponding quantities for ^{160}Dy are of the order of 0.54 MeV, 1.71 MeV and 2.25 MeV. The diagonalization of the mixing matrix yields the amplitudes C of the wave functions, and they are shown in the last column of Tables I and II. As one can see from these tables, the mixing induced by the pairing interaction is sizeable although the dominant component of each wave function is still the irrep considered in the restricted model space.

Naturally, and in order to estimate the effect of this mixing upon the double beta decay process, we should compute explicitly the corresponding matrix elements, which are the sum of products of amplitudes and individual matrix elements. It will be done in the following sections.

IV. THE $\beta\beta_{2\nu}$ HALF-LIFE

The inverse half-life of the two neutrino mode of the $\beta\beta$ -decay, $\beta\beta_{2\nu}$, can be cast in the form [37]

$$\left[\tau_{2\nu}^{1/2}(0^+ \rightarrow 0^+) \right]^{-1} = G_{2\nu} |M_{2\nu}|^2. \quad (15)$$

where $G_{2\nu}$ is a kinematical factor which depends on $Q_{\beta\beta}$, the total kinetic energy released in the decay.

The nuclear matrix element is written

$$M_{2\nu} \approx M_{2\nu}^{GT} = \sum_N \frac{\langle 0_f^+ || \Gamma || 1_N^+ \rangle \langle 1_N^+ || \Gamma || 0_i^+ \rangle}{\mu_N}, \quad (16)$$

with the Gamow-Teller operator Γ expressed as

$$\Gamma_m = \sum_s \sigma_{ms} t_s^- \equiv \sum_{\pi\nu} \sigma(\pi, \nu) [a_{\eta_\pi l_\pi \frac{1}{2}; j_\pi}^\dagger \otimes \tilde{a}_{\eta_\nu l_\nu \frac{1}{2}; j_\nu}]_m^1, \quad m = 1, 0, -1. \quad (17)$$

The energy denominator is $\mu_N = E_f + E_N - E_i$ and it contains the intermediate E_N , initial E_i and final E_f energies. The kets $|1_N^+\rangle$ denote intermediate states.

The mathematical expressions needed to evaluate the nuclear matrix elements of the allowed $g.s. \rightarrow g.s.$ $\beta\beta$ decay in the pseudo SU(3) model were developed in [17]. Using the summation method described in [17, 38], exploiting the fact that the two body terms of the $SU(3)$ Hamiltonian commute with the Gamow-Teller operator (17) [18], resumming the infinite series and recoupling the Gamow-Teller operators, the following expression was found:

$$M_{2\nu}^{GT} = \sqrt{3} \sum_{\pi\nu, \pi'\nu'} \frac{\sigma(\pi, \nu)\sigma(\pi', \nu')}{(E_0 + \epsilon_\pi - \epsilon_{\nu'})} \langle 0_f^+ | [a_\pi^\dagger \otimes \tilde{a}_\nu]^1 \otimes [a_{\pi'}^\dagger \otimes \tilde{a}_{\nu'}]^1 \rangle^{J=0} | 0_i^+ \rangle \quad (18)$$

where $\pi \equiv (\eta_\pi, l_\pi, j_\pi)$ and $\nu \equiv (\eta_\nu, l_\nu, j_\nu)$, and $E_0 = \frac{Q_{\beta\beta}}{2} + m_e c^2$.

In the following we shall analyze the nuclear matrix element (18) for the $\beta\beta_{2\nu}$ decay of the ground state of ^{160}Gd , Eq. (7), to the ground state of ^{160}Dy , Eq.(8). Each Gamow-Teller operator (17) annihilates a proton and creates a neutron in the same oscillator shell and with the same orbital angular momentum. In the case of the $\beta\beta$ of ^{160}Gd it means that the operator annihilates two neutrons in the pseudo shell $\eta_\nu = 5$ and creates two protons in the abnormal orbit $h_{11/2}$. As a consequence the only orbitals which in the model space can be connected by the $\beta\beta$ decay are those satisfying $\eta_\pi = \eta_\nu \equiv \eta$, that implies $l_\pi = l_\nu = \eta$, $j_\nu = \eta - \frac{1}{2}$ and $j_\pi = \eta + \frac{1}{2}$.

Under these restrictions the $\beta\beta_{2\nu}$ decay is allowed only if the occupation numbers obey the following relationships

$$\begin{aligned} n_{\pi, f}^A &= n_{\pi, i}^A + 2, & n_{\nu, f}^A &= n_{\nu, i}^A, \\ n_{\pi, f}^N &= n_{\pi, i}^N, & n_{\nu, f}^N &= n_{\nu, i}^N - 2. \end{aligned} \quad (19)$$

It follows that, when using the restricted configuration space in Eq. (18), only one term in the sum survives and thus the nuclear matrix element $M_{2\nu}$ (18) can be written as

$$M_{2\nu}^{GT} = \frac{\sigma(\pi, \nu)^2}{\mathcal{E}} \langle 0_f^+ | [a_\pi^\dagger \otimes \tilde{a}_\nu]^1 \otimes [a_\pi^\dagger \otimes \tilde{a}_\nu]^1 \rangle^{J=0} | 0_i^+ \rangle, \quad (20)$$

where the energy denominator $\mathcal{E}$ is determined by demanding that the energy of the Isobaric Analog State equals the difference in Coulomb energies Δ_C . It is given by [17]

$$\mathcal{E} = E_0 + \epsilon(\eta_\pi, l_\pi, j_\pi = j_\nu + 1) - \epsilon(\eta_\nu, l_\nu, j_\nu) = E_0 - \hbar\omega k_\pi 2j_\pi + \Delta_C. \quad (21)$$

$$\Delta_C = \frac{0.70}{A^{1/3}} [2Z + 1 - 0.76((Z + 1)^{4/3} - Z^{4/3})] \text{MeV}.$$

As it was discussed in [17], Eq. (20) has no free parameters, being the denominator (21) a well defined quantity. The reduction to only one term is a consequence of the restricted Hilbert proton and neutron spaces of the model. The initial and final ground states are strongly correlated with a very rich structure in terms of their shell model components.

The low energy levels are assumed to have pseudo spin $\tilde{S} = 0$, a fact that again simplifies the evaluation of the above sum since $\tilde{L} = J$.

The calculation of the matrix elements, Eq. (20), in the normal space is performed by using $SU(3)$ Racah calculus to decouple the proton and neutron normal irreps, and expanding the annihilation operators in their SU(3) tensorial components. For the particular case of ^{160}Gd , in the spirit of the single model space of subsection III.A, the $\beta\beta_{2\nu}$ decay can reach only the second component of the wave function of the ground state of ^{160}Dy (8), and for this reason it is

proportional to the amplitude b . The expression for the matrix elements of the $\beta\beta_{2\nu}$ channel reads

$$M_{2\nu}^{GT}(^{160}\text{Gd} \rightarrow ^{160}\text{Dy}) = b \frac{2j_\pi - 1}{2j_\pi} \left[\frac{(n_\pi^A + 2)(2j_\pi + 1 - n_\pi^A)}{j_\pi - 1} \right]^{1/2} \mathcal{E}^{-1} \sum_{(\lambda_0, \mu_0)} \langle (0\tilde{\eta})1\tilde{l}, (0\tilde{\eta})1\tilde{l} \| (\lambda_0\mu_0)10 \rangle_1 \sum_{\rho} \langle (28, 8)1\ 0, (\lambda_0, \mu_0)1\ 0 \| (28, 4)10 \rangle_{\rho} \sum_{\rho'} \begin{bmatrix} (10, 4) & (0, 0) & (10, 4) & 1 \\ (18, 4) & (\lambda_0\mu_0) & (18, 0) & \rho' \\ (28, 8) & (\lambda_0\mu_0) & (28, 4) & \rho \\ 1 & 1 & 1 & \end{bmatrix} \langle (18, 0) \parallel [\tilde{a}_{0\tilde{\eta}}, \frac{1}{2}\tilde{a}_{0\tilde{\eta}}, \frac{1}{2}]^{(\lambda_0\mu_0)} \parallel (18, 4) \rangle_{\rho'}. \quad (22)$$

In the so-called large model space, of subsection III.B, the expression for the matrix element of the $\beta\beta_{2\nu}$ decay mode is

$$M_{2\nu}^{GT}(^{160}\text{Gd} \rightarrow ^{160}\text{Dy}) = \sum_{k,l} C_k^{(i)} C_l^{(l)} \frac{2j_{\pi,k} - 1}{2j_{\pi,k}} \left[\frac{(n_{\pi,k}^A + 2)(2j_{\pi,k} + 1 - n_{\pi,k}^A)}{j_{\pi,k} - 1} \right]^{1/2} \mathcal{E}^{-1} \sum_{(\lambda_0, \mu_0)} \langle (0\tilde{\eta})1\tilde{l}, (0\tilde{\eta})1\tilde{l} \| (\lambda_0\mu_0)10 \rangle_1 \sum_{\rho} \langle (\lambda_k, \mu_k)1\ 0, (\lambda_0, \mu_0)1\ 0 \| (\lambda_l, \mu_l)10 \rangle_{\rho} \sum_{\rho'} \begin{bmatrix} (\lambda_{\pi,k}, \mu_{\pi,k}) & (0, 0) & (\lambda_{\pi,l}, \mu_{\pi,l}) & 1 \\ (\lambda_{\nu,k}, \mu_{\nu,k}) & (\lambda_0\mu_0) & (\lambda_{\nu,l}, \mu_{\nu,l}) & \rho' \\ (\lambda_k, \mu_k) & (\lambda_0\mu_0) & (\lambda_l, \mu_l) & \rho \\ 1 & 1 & 1 & \end{bmatrix} \langle (\lambda_l, \mu_l) \parallel [\tilde{a}_{0\tilde{\eta}}, \frac{1}{2}\tilde{a}_{0\tilde{\eta}}, \frac{1}{2}]^{(\lambda_0\mu_0)} \parallel (\lambda_k, \mu_k) \rangle_{\rho'}. \quad (23)$$

V. THE $\beta\beta_{0\nu}$ HALF-LIFE

For massive Majorana neutrinos one can perform the integration over the four-momentum of the exchanged particle and obtain a “neutrino potential” which for a light neutrino ($m_\nu < 10$ MeV) has the form

$$H(r, \bar{E}) = \frac{2R}{\pi r} \int_0^\infty dq \frac{\sin(qr)}{q + \bar{E}}, \quad (24)$$

where $\bar{E}$ is the average excitation energy of the intermediate odd-odd nucleus and the nuclear radius R has been added to make the neutrino potential dimensionless. In the zero neutrino case this closure approximation is well justified [39]. The final formula, restricted to the term proportional to the neutrino mass, is [4, 37]

$$(\tau_{0\nu}^{1/2})^{-1} = \left(\frac{\langle m_\nu \rangle}{m_e} \right)^2 G_{0\nu} M_{0\nu}^2. \quad (25)$$

where $G_{0\nu}$ is the phase space integral associated with the emission of the two electrons. The nuclear matrix elements $M_{0\nu}$ are [37]

$$M_{0\nu} \equiv |M_{0\nu}^{GT} - \frac{g_V^2}{g_A^2} M_{0\nu}^F|, \quad (26)$$

with

$$M_{0\nu}^\alpha = \langle 0_f^+ \| O^\alpha \| 0_i^+ \rangle, \quad (27)$$

where the kets $|0_i^+\rangle$ and $|0_f^+\rangle$ denote the corresponding initial and final nuclear states, the quantities g_V and g_A are the dimensionless coupling constants of the vector and axial vector nuclear currents, and

$$O^{GT} \equiv \sum_{m,n} O_{mn}^{GT} = \sum_{m,n} \vec{\sigma}_m t_m^- \cdot \vec{\sigma}_n t_n^- H(|\vec{r}_m - \vec{r}_n|, \bar{E}), \quad (28)$$

$$O^F \equiv \sum_{m,n} O_{mn}^F = \sum_{m,n} t_m^- t_n^- H(|\vec{r}_m - \vec{r}_n|, \bar{E}),$$

being $\vec{\sigma}$ the Pauli matrices related with the spin operator and t^- the isospin lowering operator, which satisfies $t^-|n\rangle = |p\rangle$. The superindex GT denotes the Gamow-Teller operator, while F indicates the Fermi operator. In the present work we use the effective value $(\frac{g_A}{g_V})^2 = 1.0$ [42].

Transforming the transition operators to the pseudo $SU(3)$ space, we have the formal expression

$$O^\alpha = O_{N\pi N\nu}^\alpha + O_{N\pi A\nu}^\alpha + O_{A\pi N\nu}^\alpha + O_{A\pi A\nu}^\alpha \quad (29)$$

where the subscript index $NN, NA, \dots$ are indicating the normal or abnormal spaces of the nucleon creation and annihilation operators, respectively. Given that we use the Nilsson scheme to obtain the occupation numbers, we are considering only nucleon pairs. For this reason only the four type of transitions listed above give a non-vanishing contribution to the $\beta\beta_{2\nu}$ matrix elements.

In a previous work we have restricted our analysis to six potential double beta emitters which, within the approximations of the simplest pseudo $SU(3)$ scheme, are also decaying via the $2\nu \beta\beta$ mode. They include the observed $^{150}\text{Nd} \rightarrow ^{150}\text{Sm}$ and $^{238}\text{U} \rightarrow ^{238}\text{Pu}$ $\beta\beta_{2\nu}$ decays. In this case two neutrons belonging to a normal parity orbital decay in two protons belonging to an abnormal parity orbital. The transition is mediated by the operator $O_{A\pi N\nu}^\alpha$. Under the seniority zero assumption for nucleons in abnormal parity orbitals, only proton pairs coupled to $J=0$ are allowed in the ground state. The matrix elements is

$$\begin{aligned} M_{0\nu}^\alpha(A_\pi N_\nu) &\equiv \sum_{j_\nu} M_{0\nu}^\alpha(A_\pi N_\nu, j_\nu) = - \sum_{j_\nu} \sqrt{\frac{2j_\nu+1}{2(2l_\nu+1)}} \sqrt{\frac{(n_\pi^A+2)(2j_\pi+1-n_\pi^A)}{2j_\pi+1}} \langle (j_\pi^A j_\pi^A) J = M = 0 | O^\alpha | (j_\nu j_\nu) J = M = 0 \rangle \\ &\quad \sum_{K_\pi L_\pi} \sum_{K_\nu K'_\nu} \langle (\lambda_\pi^f, \mu_\pi^f) K_\pi L_\pi, (\lambda_\nu^f, \mu_\nu^f) K'_\nu L_\pi \| (\lambda_\pi^i, \mu_\pi^i) K_\pi L_\pi, (\lambda_\nu^i, \mu_\nu^i) K_\nu L_\pi \| (\lambda_\pi^i, \mu_\pi^i) 10 \rangle \\ &\quad \sum_{(\lambda_0, \mu_0) \rho_0} \langle (\lambda_\nu^i, \mu_\nu^i) K_\nu L_\nu, (\lambda_0, \mu_0) 10 \| (\lambda_\nu^f, \mu_\nu^f) K'_\nu L_\nu \rangle_{\rho_0} \langle (0, \tilde{\eta}_\nu) 1 \tilde{l}_\nu, (0, \tilde{\eta}_\nu) 1 \tilde{l}_\nu \| (\lambda_0, \mu_0) 10 \rangle \\ &\quad \langle (\lambda_\nu^f, \mu_\nu^f) \| [\tilde{a}_{(0, \tilde{\eta}_\nu) \tilde{l}_\nu; \frac{1}{2}} \tilde{a}_{(0, \tilde{\eta}_\nu) \tilde{l}_\nu; \frac{1}{2}}]^{(\lambda_0, \mu_0); \tilde{S}=0} \| (\lambda_\nu^i, \mu_\nu^i) \rangle_{\rho_0}. \end{aligned} \quad (30)$$

We have implicitly defined $M_{0\nu}^\alpha(j_\nu)$ as the contribution of each normal parity neutron state j_ν to the nuclear matrix element in the transition $(j_\nu)^2 \rightarrow (j_\pi^A)^2$.

The transitions which are forbidden for the $\beta\beta_{2\nu}$ decay are allowed for the zero neutrino mode, due to presence of the neutrino potential, instead. In the simplest model space, the $\beta\beta_{0\nu}$ of ^{160}Gd has finite contributions for the two components with different occupation numbers in the ^{160}Dy final state. There are two terms in the $\beta\beta_{0\nu}$ decay: one to the basis state which has allowed $\beta\beta_{2\nu}$ decay, and one to the state with forbidden $\beta\beta_{2\nu}$ decay. In the first case the above equation must be used. The second case involves the annihilation of two neutrons in normal parity orbitals, and the creation of two protons in normal parity orbitals. This transition is mediated by the operator $O_{N\pi N\nu}^\alpha$. The $\beta\beta_{0\nu}$ matrix element has the form

$$\begin{aligned} M_{0\nu}^\alpha(N_\pi N_\nu) &\equiv \sum_J M_{0\nu}^\alpha(N_\pi N_\nu, J) = -\frac{1}{4} \sum_{j_\pi j_{\pi'} j_\nu j_{\nu'}} \sqrt{(2j_\pi+1)(2j_{\pi'}+1)(2j_\nu+1)(2j_{\nu'}+1)} \\ &\quad \sum_J \sqrt{2J+1} \langle (j_\pi j_{\pi'}) J | O^\alpha | (j_\nu j_{\nu'}) J \rangle W(\tilde{l}_\pi J \frac{1}{2} j_{\pi'}, \tilde{l}_{\pi'} j_\pi) W(\tilde{l}_\nu J \frac{1}{2} j_{\nu'}, \tilde{l}_{\nu'} j_\nu) \\ &\quad \sum_{(\lambda_0^\pi, \mu_0^\pi) K_0^\pi} \langle (\tilde{\eta}_\pi, 0) 1 \tilde{l}_\pi, (\tilde{\eta}_\pi, 0) 1 \tilde{l}_{\pi'} \| (\lambda_0^\pi, \mu_0^\pi) K_0^\pi J \rangle \sum_{(\lambda_0^\nu, \mu_0^\nu) K_0^\nu} \langle (0, \tilde{\eta}_\nu) 1 \tilde{l}_\nu, (0, \tilde{\eta}_\nu) 1 \tilde{l}_{\nu'} \| (\lambda_0^\nu, \mu_0^\nu) K_0^\nu J \rangle \\ &\quad \sum_{(\lambda_0, \mu_0) \rho_0} \langle (\lambda_0^\pi, \mu_0^\pi) K_0^\pi J, (\lambda_0^\nu, \mu_0^\nu) K_0^\nu J \| (\lambda_0, \mu_0) 10 \rangle_{\rho_0} \sum_\rho \langle (\lambda^i, \mu^i) 10, (\lambda_0, \mu_0) 10 \| (\lambda^f, \mu^f) 10 \rangle_\rho \\ &\quad \sum_{\rho_\pi \rho_\nu} \begin{bmatrix} (\lambda_\pi^i, \mu_\pi^i) & (\lambda_0^\pi, \mu_0^\pi) & (\lambda_\pi^f, \mu_\pi^f) & \rho_\pi \\ (\lambda_\nu^i, \mu_\nu^i) & (\lambda_0^\nu, \mu_0^\nu) & (\lambda_\nu^f, \mu_\nu^f) & \rho_\nu \\ (\lambda^i, \mu^i) & (\lambda_0, \mu_0) & (\lambda^f, \mu^f) & \rho \\ 1 & \rho_0 & 1 & \end{bmatrix} \langle (\lambda_\pi^f, \mu_\pi^f) \| [a_{\tilde{\eta}_\pi, 0, \frac{1}{2}}^\dagger a_{\tilde{\eta}_\pi, 0, \frac{1}{2}}^\dagger]^{(\lambda_0^\pi, \mu_0^\pi); \tilde{S}=0} \| (\lambda_\pi^i, \mu_\pi^i) \rangle_{\rho_\pi} \\ &\quad \langle (\lambda_\nu^f, \mu_\nu^f) \| [\tilde{a}_{(0, \tilde{\eta}_\nu) \tilde{l}_\nu; \frac{1}{2}} \tilde{a}_{(0, \tilde{\eta}_\nu) \tilde{l}_\nu; \frac{1}{2}}]^{(\lambda_0^\nu, \mu_0^\nu); \tilde{S}=0} \| (\lambda_\nu^i, \mu_\nu^i) \rangle_{\rho_\nu}. \end{aligned} \quad (31)$$

In the above expression the $W(\dots, \dots)$ are Racah Coefficients [43]. The two-body matrix element can be expanded in its L, S components

$$\begin{aligned} &\langle (j_\pi j_{\pi'}) J | O^\alpha | (j_\nu j_{\nu'}) J \rangle = \\ &\sum_{LS} \chi \left\{ \begin{matrix} l_\pi & l_{\pi'} & L \\ \frac{1}{2} & \frac{1}{2} & S \\ j_\pi & j_{\pi'} & J \end{matrix} \right\} \chi \left\{ \begin{matrix} l_\nu & l_{\nu'} & L \\ \frac{1}{2} & \frac{1}{2} & S \\ j_\nu & j_{\nu'} & J \end{matrix} \right\} \langle (l_\pi l_\pi) L \| H(r, \vec{E}) \| (l_\nu l_\nu) L \rangle \langle (\frac{1}{2} \frac{1}{2}) S \| \Gamma \cdot \Gamma(\alpha) \| (\frac{1}{2} \frac{1}{2}) S \rangle \end{aligned} \quad (32)$$

where the $\chi \{...\}$ are Jahn-Hope coefficients [43] and

$$\Gamma \cdot \Gamma(GT) \equiv \vec{\sigma}_1 \cdot \vec{\sigma}_2 \quad \Gamma \cdot \Gamma(F) \equiv 1 \quad \alpha = GT \text{ or } F. \quad (33)$$

In order to evaluate the spatial matrix elements, we have used the Bessel-Fourier expansion of the potential [44], which gives

$$\langle (l_1 l_2) LM | H(r) | (l_3 l_4) LM \rangle = \sum_l (-1)^{l_1 + l_4 + L} (2l + 1) (l_1 \| C_l \| l_3) (l_2 \| C_l \| l_4) W(l_1 l_2 l_3 l_4; L l) R^l(l_1 l_2, l_3 l_4) \quad (34)$$

where $(l_i \| C_l \| l_j)$ are the reduced matrix elements of the unnormalized spherical harmonics $C_{lm}(\Omega) \equiv \sqrt{\frac{4\pi}{2l+1}} Y_{lm}(\Omega)$ and $R^l(l_1 l_2, l_3 l_4)$ are the radial integrals described in Appendix A of Ref. [18]. They include the effects of the finite nucleon size and the short range correlations, as explained in Appendix C of Ref. [18].

The zero neutrino $\beta\beta$ matrix element has, as mentioned above, contributions from the two components of the ^{160}Dy wave function:

$$M_{0\nu}^\alpha = a M_{0\nu}^\alpha(N_\pi N_\nu) + b M_{0\nu}^\alpha(A_\pi N_\nu) \quad (35)$$

As said before, these expressions are to be supplemented by other contributions, $M_{0\nu}^\alpha(N_\pi A_\nu)$ and $M_{0\nu}^\alpha(A_\pi A_\nu)$, when the large model space (of subsection III.B) is used to construct the initial and final wave functions. The expression of the additional terms is similar to the ones of the above equations and they are omitted for the sake of brevity. The matrix element of the $\beta\beta_{0\nu}$ mode is thus given by

$$M_{0\nu}^\alpha = \sum_{k,l} C_k^{(i)} C_l^{(f)} M_{0\nu}^\alpha(k, l), \quad (36)$$

where the indexes k and l denote the set of quantum numbers needed to specify the occupations and irreps included in the wave functions.

VI. THE $\beta\beta$ OF ^{160}Gd

In this section we study the two neutrino and zero neutrino modes of the double beta decay of ^{160}Gd to the ground state of ^{160}Dy .

In the restricted configuration space of subsection III.A, the ground state of ^{160}Dy , defined in Eq.(8), is a linear combination of two states having different occupation numbers. The energy difference between these states, estimated from the difference in their deformed Nilsson single particle energies, is $\Delta E = 1.71$ MeV. The pairing mixing between them, using the interaction strength $G_\pi = 21/A$ MeV, is $h_{pair} = 0.865$ MeV. With these matrix elements, the diagonalization of Eq. (9) yields the amplitudes $a = 0.923$, $b = 0.385$ of the wave function of the ground state of ^{160}Dy .

The $\beta\beta_{2\nu}$ matrix element is suppressed by a factor b , compared with the *allowed* decays. It implies that the $\beta\beta_{2\nu}$ half-life is an order of magnitude $(1/b^2)$ larger than in other nuclei with similar $Q_{\beta\beta}$ values. The energy denominator takes the value $\mathcal{E} = 12.19$ MeV. The two neutrino $\beta\beta$ matrix element is $M_{2\nu}^{GT}(^{160}\text{Gd} \rightarrow ^{160}\text{Dy}) = 0.0455$ MeV $^{-1}$. The phase space integral is $G_{GT} = 8.028 \times 10^{-20}$ MeV 2 yr $^{-1}$, using $g_A/g_V = 1.0$. The estimated $\beta\beta_{2\nu}$ half-life is

$$\tau_{2\nu}^{1/2}(^{160}\text{Gd} \rightarrow ^{160}\text{Dy}) = 6.02 \times 10^{21} \text{ yr}. \quad (37)$$

The contribution of the different angular momentum J to the matrix elements $M_{0\nu}^\alpha(N_\pi N_\nu, J)$, in Eq. (35), are shown in Table III.

It is remarkable that the $J=0$ channel largely dominates both the Fermi (F) and Gamow-Teller (GT) transitions. The $J = 2$ channel tends to reduce the transition matrix elements by about 20 to 30 %, For the Fermi matrix elements, the $J = 4$ channel also contributes noticeably. Fermi and Gamow-Teller matrix elements add coherently due to the sign inversion in Eq. (26).

The transition matrix elements from the different neutron single particle angular momentum j_ν in the matrix elements $M_{0\nu}^\alpha(A_\pi N_\nu, j_\nu)$, are presented in Table IV. In this case two neutrons are annihilated in the normal parity orbitals $p_{1/2}, p_{3/2}, f_{5/2}, f_{7/2}, h_{9/2}$ and two protons are created in the intruder orbit $h_{11/2}$.

As seen in Table IV, both for the Fermi and Gamow-Teller matrix elements the terms add coherently. While in the Gamow-Teller case the $h_{9/2} \rightarrow h_{11/2}$ transition clearly dominates, in the Fermi case all transitions amplitudes are

J	F	GT
0	-0.11746	0.25588
2	0.03792	-0.05016
3	-0.00131	-0.00011
4	0.02090	0.00454
6	0.00312	0.00501
Sum	-0.05683	0.21516
$M_{0\nu}(N_\pi N_\nu) = 0.27199$		

TABLE III: $M_{0\nu}^\alpha(N_\pi N_\nu, J)$ for the $\beta\beta_{0\nu}$ of ^{160}Gd .

j_ν	F	GT
$p_{1/2}$	0.01552	-0.06792
$p_{3/2}$	0.02105	-0.05359
$f_{5/2}$	0.02168	-0.16133
$f_{7/2}$	0.06341	-0.11847
$h_{9/2}$	0.04310	-1.16598
Sum	0.16477	-1.56729
$M_{0\nu}(A_\pi N_\nu) = -1.73206$		

TABLE IV: $M_{0\nu}^\alpha(A_\pi N_\nu, j_\nu)$ for the $\beta\beta_{0\nu}$ of ^{160}Gd .

comparable. As in Table III, Fermi and Gamow-Teller final matrix elements add coherently. In absolute value, the *allowed* $\beta\beta_{0\nu}$ transition matrix element $M_{0\nu}(A_\pi N_\nu)$ is a factor 6 larger than the *forbidden* one $M_{0\nu}(N_\pi N_\nu)$. The final $\beta\beta_{0\nu}$ matrix element is

$$M_{0\nu}(^{160}\text{Gd} \rightarrow ^{160}\text{Dy}) = a M_{0\nu}(N_\pi N_\nu) + b M_{0\nu}(A_\pi N_\nu) = 0.251 + 0.668 = 0.919. \quad (38)$$

The zero neutrino phase space integral for the $\beta\beta_{0\nu}$ of ^{160}Gd is $G_{0\nu} = 1.480 \times 10^{-14} \text{ yr}^{-1}$. Expressing the Majorana mass of the neutrino $\langle m_\nu \rangle$ in units of eV, the calculated zero neutrino $\beta\beta$ half-life is

$$\tau_{0\nu}^{1/2}(^{160}\text{Gd} \rightarrow ^{160}\text{Dy}) \cdot \langle m_\nu \rangle^2 = 2.09 \times 10^{25} \text{ yr}. \quad (39)$$

This half-life is a factor 20 larger than the one reported in [40]. The difference is easily understood, given the fact that the present model takes explicitly into account the nuclear deformation, while in [40] the spherical QRPA was used to obtain a crude estimations of the half-lives of all potential $\beta\beta$ emitters.

As mentioned above, the parameter ΔE , which strongly influences the pairing mixing, is taken from the deformed Nilsson single particle energies. To estimate in which extent changes in this parameter affect the predicted double-beta-decay half-lives, we have allowed it to vary from 1.1 MeV to 2.5 MeV, covering most of the physically reasonable range. The results are listed in Table V.

The mixing parameter b and the double-beta-decay matrix elements and half-lives are very smooth functions of ΔE . The two neutrino double-beta-decay half-life varies between $4 \times 10^{21} \text{ yr}$ and $10 \times 10^{21} \text{ yr}$, around the predicted value of $6 \times 10^{21} \text{ yr}$. The calculated half-life of the neutrinoless double-beta-decay is less dependent upon the mixing induced by pairing and it varies in the range $1.5 - 2.9 \times 10^{25} \text{ yr}$.

Concerning the results obtained in the enlarged space of subsection III.B, we are presenting them in Table VI. The partial contributions to the $\beta\beta_{2\nu}$ and $\beta\beta_{0\nu}$ decay processes, for transitions between the components of the initial and final wave functions, are listed in this table. We are indicating, also, the character of each of the transitions, with regard to the type of orbital, abnormal (A) or normal (N), of the neutrons and protons involved in the decay.

For the case of the $\beta\beta_{2\nu}$ decay mode, there are four active configurations and each of them add coherently to the final matrix element. They are partially suppressed by their amplitudes and the final matrix element is of the order of 0.086 MeV^{-1} . This value is about twice the one obtained by using the small configuration space of subsection III.A. Consequently, the calculated half-life, which is of the order of $1.68 \times 10^{21} \text{ yrs}$, is shorter than the one obtained in the small space. Concerning the $\beta\beta_{0\nu}$ decay mode, the results shown in Table VI indicate that there is an interference between configurations where both nucleons are in intruder orbits and those where the proton occupies an intruder orbit. For this channel the resulting matrix element is of the order of 0.293, a value which is about a factor three smaller than the one obtained in the small configuration space. The predicted half-life

$$\tau_{0\nu}^{1/2}(^{160}\text{Gd} \rightarrow ^{160}\text{Dy}) \cdot \langle m_\nu \rangle^2 = 2.05 \times 10^{26} \text{ yr}, \quad (40)$$

$\Delta E[\text{MeV}]$	b	$M_{2\nu}^{GT} [\text{MeV}^{-1}]$	$\tau_{2\nu}^{1/2} [10^{21} \text{ yr}]$	$M_{0\nu}$	$\tau_{0\nu}^{1/2} [10^{25} \text{ yr}]$

TABLE VI: Matrix elements for the $\beta\beta_{2\nu}$ and $\beta\beta_{0\nu}$ decay modes. Each arrow shows the participant configurations, of the initial and final wave functions, which are listed in Tables I and II. The transitions not included in the table are trivially forbidden because they imply the change of the states of more than two nucleons. The $\beta\beta_{2\nu}$ transitions listed as “not allowed”, are the ones which are forbidden by the selection rules discussed in section IV. The matrix elements of the $\beta\beta_{2\nu}$ mode are given in units of MeV^{-1} .

is an order of magnitude larger than the one obtained in the small configuration space.

The above presented results can be summarized by noticing that the effect of including occupations others than the most probable one is less crucial for the two-neutrino mode than for the case of the neutrinoless double beta decay. Nevertheless, the predicted two-neutrino double beta decay of ^{160}Gd is still suppressed, as compared to other double beta decay emitters. In this respect, the results of the present calculations are an improvement of earlier ones [17], where claims about a suppression of the two-neutrino mode have been made. Here, we have used a larger configuration space, as explained before, instead of a single configuration. The two neutrino double beta decay in ^{160}Gd is hindered by nuclear structure effects, and the predicted half-life is of the order of $10^{21(22)}$ yr, depending upon the model space. The zero neutrino double-beta-decay half-life is at least three to four orders of magnitude larger. In view of these predicted values, we are confident that the planned experiments using GSO crystals [24] would definitely be able to detect the $\beta\beta_{2\nu}$ decay of ^{160}Gd , and could establish competitive limits to the $\beta\beta_{0\nu}$ decay. The background suppression due to a large $\beta\beta_{2\nu}$ half-life would be effective, although not as noticeably as was optimistically envisioned in [24].

Results about selection rules in other deformed double beta decay emitters are reported in [45].

VII. CONCLUSIONS

In the present paper we have studied the $\beta\beta_{2\nu}$ and $\beta\beta_{0\nu}$ decay modes of ^{160}Gd to the ground states of ^{160}Dy . The transitions have been analyzed in the context of the pseudo SU(3) model.

The energy spectrum and electromagnetic transitions in ^{160}Gd and ^{160}Dy have been studied in detail, in previous works, using the pseudo SU(3) model and a realistic Hamiltonian. Ground state wave functions were built as linear combinations of the pseudo SU(3) irreps associated with the larger quadrupole deformations, in a model space with fixed occupation numbers in normal and unique parity orbitals. Nucleons occupying intruder orbits were frozen. The pseudo SU(3) leading irrep typically carries 60% of the total wave function.

In the present contribution the mixing of different occupation numbers in the ^{160}Dy ground state wave function was studied. Only leading irreps, for each occupation, were considered in the calculations. The mixing induced by the pairing interaction makes possible the two neutrino double beta decay of ^{160}Gd , which is forbidden when only the most probable occupation numbers are used.

Explicit expressions are presented for the pairing mixing, and for the $\beta\beta_{2\nu}$ and $\beta\beta_{0\nu}$ nuclear matrix elements in the present pseudo SU(3) approach. The estimated $\beta\beta$ half-lives are larger than those obtained using a spherical QRPA model, and the results suggest that the planned experiments would succeed in detecting the $\beta\beta_{2\nu}$ decay in ^{160}Gd , and in setting competitive limits for the zero neutrino mode.
